

Sleep-frailty decomposition: latent-factor LDSC estimates

Secondary sensitivity family · points show rg; bars show Wald 95% CIs · * BH q ≤ 0.05 across 84 pairs

Insomnia is one of the 30 deficits used to construct the general factor; that pairing has direct part-whole dependence. Exact participant overlap is unknown. Estimates do not establish independent replication, differences between correlated endpoints, or causation. Physical components, Fried phenotype and HFRS are not represented: eligible sleep-pair estimates are unavailable.
